# The Structure of Management Information (SMI)

## 1 Background

The SNMP protocol is called “simple” because the protocol itself is quite simple. However, the difficulty is in applying it to actually managing systems and networks.

There are many terms and standards involved; it is necessary to understand enough of them to make sense of the MIBs that define the objects that you want to monitor and manage. If you can make sense of the MIB files, you can identify the objects that you want to monitor.

### 1.1 Management Information Base (MIB)

The MIB]s define the objects that you can manage.

When you installed the Net SNMP software package, you installed some MIB files into the directory `/usr/share/snmp/mibs/`. You can list them all with:

```
$ rpm -ql ucd-snmp | grep snmp/mibs/.*\.txt
```

There are many other MIBs that are not included here; you can download others from somewhere such as `http://www.simpleweb.org/ietf/` and include them into your Net SNMP clients as explained at `http://net-snmp.sourceforge.net/FAQ.html#How_do_I_add_a_MIB_` and at `http://net-snmp.sourceforge.net/tutorial/commands/mib-options.html`.

### 1.2 Management Database (MDB)

The MIBs define what actual information the MDB may contain. The management database is a real database, and holds the actual data, whos format is defined by the MIB, stored in the agent or manager. It contains the measured or administratively configured values of the elements of the network.

### 1.3 Structure of Management Information

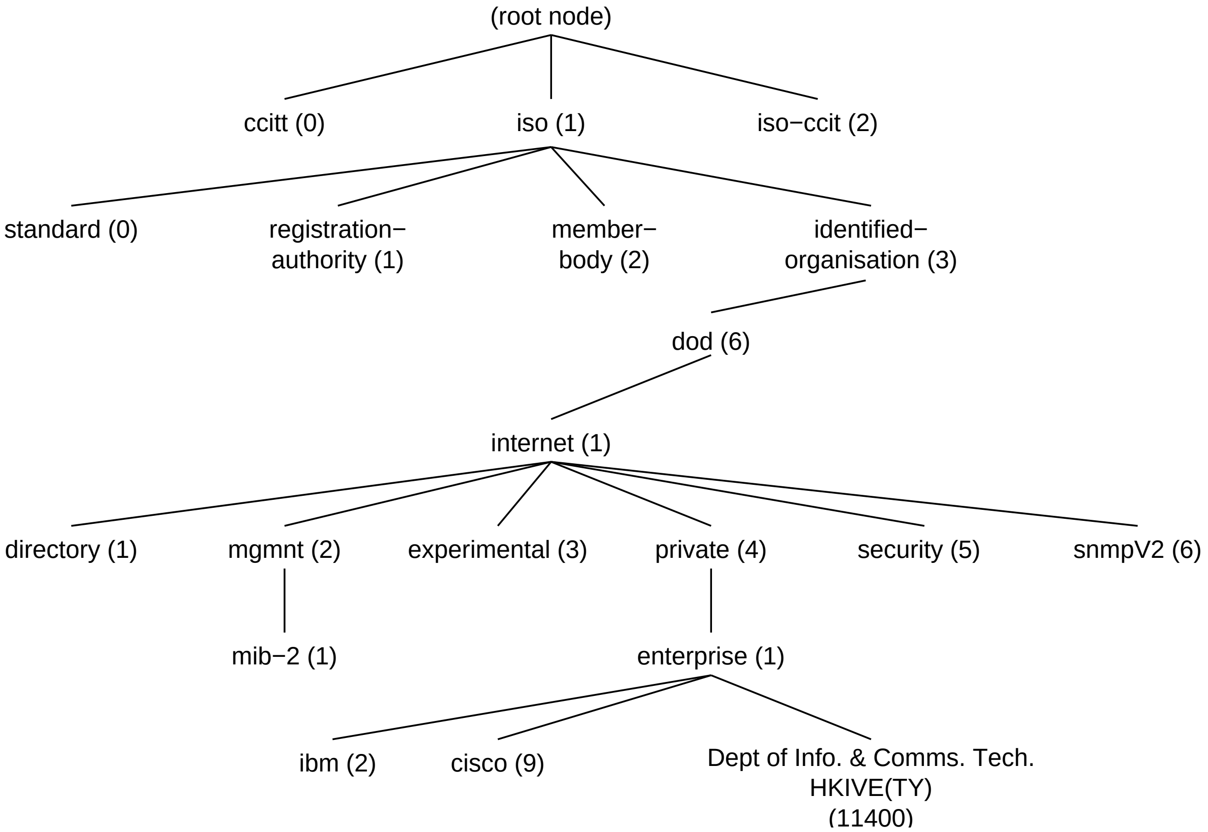

Figure 1: The Structure of Management Information Object Tree.

SMI is a definition of the structure of the MIBs, how they are connected together into a tree, as shown in figure 1. See the RFCs below in section 2.1 on page 14. It specifies which part of ASN.1 will be used to define MIBs. The MIB that defines SMI is shown here:

```
RFC1155-SMI DEFINITIONS ::= BEGIN

EXPORTS -- EVERYTHING
        internet, directory, mgmt,
        experimental, private, enterprises,
        OBJECT-TYPE, ObjectName, ObjectSyntax, SimpleSyntax
        ApplicationSyntax, NetworkAddress, IpAddress,
        Counter, Gauge, TimeTicks, Opaque;

 -- the path to the root

 internet      OBJECT IDENTIFIER ::= { iso org(3) dod(6) 1

 directory     OBJECT IDENTIFIER ::= { internet 1 }

 mgmt          OBJECT IDENTIFIER ::= { internet 2 }

 experimental  OBJECT IDENTIFIER ::= { internet 3 }

 private       OBJECT IDENTIFIER ::= { internet 4 }
 enterprises   OBJECT IDENTIFIER ::= { private 1 }

 -- definition of object types

 OBJECT-TYPE MACRO ::=
 BEGIN
     TYPE NOTATION ::= "SYNTAX" type (TYPE ObjectSyntax)
                       "ACCESS" Access
                       "STATUS" Status
     VALUE NOTATION ::= value (VALUE ObjectName)

     Access ::= "read-only"
                     | "read-write"
                     | "write-only"
                     | "not-accessible"
     Status ::= "mandatory"
                     | "optional"
                     | "obsolete"
 END
```

```
-- names of objects in the MIB

ObjectName ::=
    OBJECT IDENTIFIER

-- syntax of objects in the MIB

ObjectSyntax ::=
    CHOICE {
        simple
            SimpleSyntax,
-- note that simple SEQUENCEs are not directly
-- mentioned here to keep things simple (i.e.,
-- prevent mis-use).  However, application-wide
-- types which are IMPLICITly encoded simple
-- SEQUENCEs may appear in the following CHOICE

        application-wide
            ApplicationSyntax
    }

   SimpleSyntax ::=
       CHOICE {
           number
               INTEGER,
           string
               OCTET STRING,
           object
               OBJECT IDENTIFIER,
           empty
               NULL
       }
```

```
ApplicationSyntax ::=
    CHOICE {
        address
            NetworkAddress,
        counter
            Counter,
        gauge
            Gauge,
        ticks
            TimeTicks,
        arbitrary
            Opaque

-- other application-wide types, as they are
-- defined, will be added here
    }

-- application-wide types

NetworkAddress ::=
    CHOICE {
        internet
            IpAddress
    }

IpAddress ::=
    [APPLICATION 0]          -- in network-byte order
        IMPLICIT OCTET STRING (SIZE (4))

Counter ::=
    [APPLICATION 1]
        IMPLICIT INTEGER (0..4294967295)
```

```
Gauge ::=
    [APPLICATION 2]
        IMPLICIT INTEGER (0..4294967295)

TimeTicks ::=
    [APPLICATION 3]
        IMPLICIT INTEGER (0..4294967295)

Opaque ::=
    [APPLICATION 4]          -- arbitrary ASN.1 valu
        IMPLICIT OCTET STRING   --   "double-wrapped

END
```

## 1.4 Abstract Syntax Notation One (ASN.1)

ASN.1 is widely used for many things other than SNMP. See `http://asn1.elibel.tm.fr/en/uses/` for a list of some of the applications of ASN.1. There is a web site dedicated to providing information about it at `http://asn1.elibel.tm.fr/`.

## 1.5 Basic Encoding Rules (BER)

The *basic encoding rules* is an ISO standard. It describes a method for encoding values of each ASN.1 type as a string of octets.

### 1.5.1 ASN.1 Keywords used in SNMP

Table 1 on the following page lists some frequently used ASN.1 keywords.

### 1.5.2 ASN.1 Symbols and Operators

Table 2 on page 8 lists the ASN.1 symbols.

| Keyword | **Brief Description** |
|---|---|
| `BEGIN` | Start of an ASN.1 module |
| `CHOICE` | List of alternatives; used in defining SMIv1 and SMIv2 (`RFC1155-SMI` and `SNMPv2-SMI`) to define classes of datatypes (`SimpleSyntax` and `ApplicationSyntax`), and in SMIv2. |
| `DEFINITIONS` | Definition of a data type or managed object |
| `END` | End of an ASN.1 module |
| `EXPORTS` | Data types that can be exported to other modules |
| `IDENTIFIER` | A sequence of non-negative numbers |
| `IMPORTS` | Data types defined in external modules that are used in this module |
| `INTEGER` | A 32-bit integer (i.e., in the range $-2^{31}$ to $2^{31} - 1$). |
| `MACRO` | Required for defining macros, such as the `OBJECT-TYPE` macro defined in `RFC1155-SMI` |
| `OBJECT IDENTIFIER` | Used to uniquely identify an object with an OID |
| `OCTET` | An eight-bit binary value, used with `STRING` |
| `OCTET STRING` | A string of bytes |
| `OF` | Used with `SEQUENCE` |
| `SEQUENCE` | An ordered list of data, somewhat like a `struct` in the C language, usually used to represent a row in a table |
| `SEQUENCE OF` | A table of data. Somewhat like an array of `struct` in C |
| `STRING` | used with `OCTET` for strings of binary bytes |
| `TYPE NOTATION` | used in `MACRO` definitions to define the syntax of the new types |
| `VALUE NOTATION` | used in `MACRO` definitions to define the syntax of the new values |

Table 1: ASN.1 Keywords.

### 1.5.3 ASN.1 Data Types used in SNMP

There are three "base types" of data defined in ASN.1 used in SMI: `INTEGER`, `OCTET STRING`, and `OBJECT IDENTIFIER`.

## 1.6 Syntax of a Managed Object Definition

Every object definition in SMI has the format:

```
name OBJECT-TYPE
    SYNTAX datatype
    ACCESS either read-only, read-write, write-only. or no
    DESCRIPTION
```

| Symbol | Meaning |
|---|---|
| ::= | "defined as", or assignment |
| \| | or, alternatives, options of a list |
| - | signed number |
| -- | introduces a comment |
| { } | start and end of a list |
| [ ] | start and end of a tag |
| ( ) | start and end of a subtype |
| .. | range |

Table 2: The ASN.1 symbols.

```
        "Some text that describes this managed object."
    ::= { unique object ID that defines this object }
```

We will refer to this later in our activities.

## 2 The MIB-II Definition

Here I will refer to my edited version of `RFC1213-MIB.txt`, available at `http://sysadmin.no-ip.com/snm/lectures/smi/RFC1213-MI` `txt`. The full specification for `mib-2` is on your machine at `/usr/share/snmp/mibs/RFC1213-MIB.txt`.

```
RFC1213-MIB DEFINITIONS ::= BEGIN

IMPORTS
        mgmt, NetworkAddress, IpAddress, Counter, Gauge,
                TimeTicks
            FROM RFC1155-SMI
        OBJECT-TYPE
                FROM RFC-1212;
```

The first line defines the name of the MIB, here `RFC1213-MI`. The format of this definition is always the same.

The `IMPORTS` section of the MIB is sometimes called the *linkage* section. It lets you import definitions of datatypes and OIDs from other MIBs. Here we get the definition of:

- `mgmt`
- `NetworkAddress`
- `IpAddress`
- `Counter`
- `Gauge`
- `TimeTicks`

from `RFC1155-SMI`, the MIB from the RFC that defines SMIv1.

It also imports `OBJECT-TYPE` from `RFC-1212`, the *Concise MIB Definition*, which defines how MIB files are written.

```
mib-2      OBJECT IDENTIFIER ::= { mgmt 1 }
```

The line above says that the OID of `mib-2` is 1.3.6.1.2.1. `RFC1155-SMI` defines `mgmt` as the OID 1.3.6.1.2.

```
-- groups in MIB-II

system       OBJECT IDENTIFIER ::= { mib-2 1 }
interfaces   OBJECT IDENTIFIER ::= { mib-2 2 }
at           OBJECT IDENTIFIER ::= { mib-2 3 }
ip           OBJECT IDENTIFIER ::= { mib-2 4 }
icmp         OBJECT IDENTIFIER ::= { mib-2 5 }
tcp          OBJECT IDENTIFIER ::= { mib-2 6 }
udp          OBJECT IDENTIFIER ::= { mib-2 7 }
egp          OBJECT IDENTIFIER ::= { mib-2 8 }
transmission OBJECT IDENTIFIER ::= { mib-2 10 }
snmp         OBJECT IDENTIFIER ::= { mib-2 11 }
```

So here the `system` group is defines as the OID 1.3.6.1.2.1.1, and so on. A comment is a line starting with `--`.

```
-- the Interfaces table

-- The Interfaces table contains information on the entity's
-- interfaces.  Each interface is thought of as being
-- attached to a ‘subnetwork’.  Note that this term should
-- not be confused with ‘subnet’ which refers to an
-- addressing partitioning scheme used in the Internet suite
-- of protocols.

ifTable OBJECT-TYPE
    SYNTAX  SEQUENCE OF IfEntry
    ACCESS  not-accessible
    STATUS  mandatory
    DESCRIPTION
            "A list of interface entries.  The number of
            entries is given by the value of ifNumber."
    ::= { interfaces 2 }
```

This is the first managed object shown here. ifTable represents a table of network interfaces on a managed device. Notice that object names are defined with mixed case, the first letter is lowercase.

Notice that this follows the format of an OBJECT-TYPE in section 1.6 on page 7.

The SYNTAX of ifTable is SEQUENCE OF IfEntry. The object is not-accessible, which means that you cannot query the agent for the value of this object. It has a STATUS of mandatory, which means that if an agent complies wiht the MIBB-II specification, then it must implement this object. The DESCRIPTION tells you what this object is. The unique OID is 1.3.6.1.2.1.2.2, or iso.org.dod.internet.mgmnt.interfaces.2.

Next, let’s look at the SEQUENCE definition, which is used with the SEQUENCE OF type in the ifTable definition.

```
IfEntry ::=
    SEQUENCE {
```

```
ifIndex
    INTEGER,
ifDescr
    DisplayString,
ifType
    INTEGER,
ifMtu
    INTEGER,
ifSpeed
    Gauge,
ifPhysAddress
    PhysAddress,
ifAdminStatus
    INTEGER,
ifOperStatus
    INTEGER,
ifLastChange
    TimeTicks,
ifInOctets
    Counter,
ifInUcastPkts
    Counter,
ifInNUcastPkts
    Counter,
ifInDiscards
    Counter,
ifInErrors
    Counter,
ifInUnknownProtos
    Counter,
ifOutOctets
    Counter,
ifOutUcastPkts
```

```
                Counter,
            ifOutNUcastPkts
                Counter,
            ifOutDiscards
                Counter,
            ifOutErrors
                Counter,
            ifOutQLen
                Gauge,
            ifSpecific
                OBJECT IDENTIFIER
        }
```

The name of the `SEQUENCE` (`IfEntry`) is mixed-case, but the first letter is capitalised, which is different from the object definition for `ifTable`. A `SEQUENCE` is a list of objects that go into one row of a table. After this, we must have `OBJECT-TYPE` definitions that define each of these variables. A table can have any number of rows. Tha agent manages the number of rows. An NMS can also add rows to a table using a *set* operation.

`IfEntry` is the data type; rather like a `struct` definition in the C language.

Let's look at `ifEntry`, the definition of what we find in the table, the actual rows of the table themselves. It looks almost the same as the definition for `ifTable`, except that it has a new clause, `INDEX`. The index is a unique value that identifies a single row in the table, like an array index. A table is rather like an array of `struct`s in C. The agent assigns these index values. If a router has eight interfaces, then `ifTable` will contain eight rows.

```
ifEntry OBJECT-TYPE
    SYNTAX  IfEntry
    ACCESS  not-accessible
    STATUS  mandatory
    DESCRIPTION
```

```
            "An interface entry containing objects at the
            subnetwork layer and below for a particular
            interface."
    INDEX   { ifIndex }
    ::= { ifTable 1 }
```

Here we now look at the definition for `ifIndex`, the first item in `IfEntry`. Notice that indexes start from 1.

```
ifIndex OBJECT-TYPE
    SYNTAX  INTEGER
    ACCESS  read-only
    STATUS  mandatory
    DESCRIPTION
            "A unique value for each interface.  Its value
            ranges between 1 and the value of ifNumber.  Th
            value for each interface must remain constant a
            least from one re-initialization of the entity'
            network management system to the next re-
            initialization."
    ::= { ifEntry 1 }
```

This object is `read-only`, which means that you can see the value, but not change it.

Here is the last object we look at from this table:

```
ifDescr OBJECT-TYPE
    SYNTAX  DisplayString (SIZE (0..255))
    ACCESS  read-only
    STATUS  mandatory
    DESCRIPTION
            "A textual string containing information about
            interface.  This string should include the name
            the manufacturer, the product name and the vers
            of the hardware interface."
    ::= { ifEntry 2 }
```

```
END
```

`ifDescr` is just a textual description of the interface.

The MIB definition finishes with `END`.

## 2.1 Where can I get the standards documents from?

The standard for SMIv1 can be downloaded from `ftp://ftp.rfc-editor.org/in-notes/rfc1155.txt`, and for —SMIv2 at `ftp://ftp.rfc-editor.org/in-notes/rfc2578.txt`. The standards for ASN.1 and BER can be downloaded from `http://asn1.elibel.tm.fr/en/standards/`.
